A BAYES RULE FOR THE SYMMETRIC MULTIPLE
COMPARISONS PROBLEM II

RAY A. WALLER AND DAVID B. DUNCAN

1. Statement of problem

This paper presents the mathematical derivation of a Bayes solution for the symmetric multiple comparisons problem presented earlier by Waller and Duncan [4]. Because the earlier paper details the model and assumptions on which the solution is based, only the functions and results needed to complete the development are stated here.

Typically the data for a multiple comparisons problem consists of \( n \) independent normally distributed treatment means \((\bar{x}_1, \bar{x}_2, \ldots, \bar{x}_n)\) which estimate \( n \) true means \((\mu_1, \mu_2, \ldots, \mu_n)\) and an independent estimate, say \( s^2_x \) with \( f_x \) degrees of freedom, of the error variance \( \sigma^2 \). Further, we suppose that each mean \( \bar{x}_i \) is based on \( r \) replications. The problem is then to choose for each of the \( h=n(n-1) \) ordered pairs of means either decision \( d^{+}_{ij} : \mu_i > \mu_j \) or decision \( d^{-}_{ij} : \mu_i \) not ranked relative to \( \mu_j \). However, Duncan [2] shows that under the assumptions of symmetry and an additive loss model, the Bayes rule for the full multiple comparisons problem is the simultaneous application of the Bayes rule to select either \( d^+_{ij} \) or \( d^-_{ij} \) for the means \((\mu_i, \mu_j)\) to all \( h \) pairs of means. Thus our major concern is to obtain the Bayes rule for selecting one of the decisions

\[
\begin{align*}
d^+_i : & \quad \mu_i > \mu_j, \\
d^-_i : & \quad \mu_i \text{ not ranked relative to } \mu_j, \end{align*}
\]

for the pair of means \((\mu_i, \mu_j)\). Following that development we state an extension of the result as the Bayes rule for the full problem.

To begin the derivation of a Bayes rule to select one of the decisions (1.1) for the pair of means \((\mu_i, \mu_j)\), we summarize the probability

---

1) Contribution #129, Statistics, Kansas Agricultural Experiment Station, Kansas State University, Manhattan, 66502.

model, the prior distribution, and the loss function. For a more complete presentation of the model the reader should refer to Waller and Duncan [4].

For reasons of location invariance we consider only solutions that depend on the means \((\bar{x}_1, \bar{x}_2, \ldots, \bar{x}_n)\) through the \((n-1)\) Helmert transformations

\[
y_{1i} = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{2}}, \quad y_{2i} = \frac{\bar{x}_1 + \bar{x}_2 - 2\bar{x}_3}{\sqrt{6}}, \quad \ldots,
\]

\[
y_{n-1} = \frac{\bar{x}_1 + \bar{x}_2 + \cdots + \bar{x}_{n-1} - (n-1)\bar{x}_n}{\sqrt{n(n-1)}}.
\]

Thus the joint probability density of our data is

\[
f(z|\theta) = \left[ \prod_{i=1}^{n-1} P_i(y_i|\eta_i, \sigma_i^2) \right] P(s^2|\sigma^2, f)
\]

where \(P_i(x|\mu, \sigma^2)\) is the density of a normal random variable with mean \(\mu\) and variance \(\sigma^2\), \(P(s^2|\sigma^2, f)\) is the chi-square density of the random variable \((s^2/\sigma^2)\) with \(f\) degrees of freedom, \(z=(y_1, y_2, \ldots, y_{n-1}, s^2_f)\), \(\eta_i = E(y_i)\), and \(\theta=(\eta_1, \eta_2, \ldots, \eta_{n-1}, \sigma^2_i)\).

The prior density is the product of \((n-1)\) independent normal densities for \((\eta_1, \eta_2, \ldots, \eta_{n-1})\), each with mean zero and variance \(\sigma_i^2\), and an independent joint density for \(\sigma^2_i\) and \(\sigma^2_{\tau} = \sigma^2 + \sigma^2_i\) (by definition) deduced from two independent \(\chi^2\) densities. Thus, the full prior density is

\[
\lambda(\theta) = K^{-1} \left[ \prod_{i=1}^{n-1} \left[ \sum_{\eta_i=0}^{\infty} P_i(y_i|\eta_i, \sigma_i^2, \sigma^2 - \sigma_i^2) \right] P(s^2_f|s^2_{\tau_f}, q_f)P(s^2|s^2_{\tau}, f) \right] d\sigma^2_f
\]

where \(P_i\) is defined for (1.2), \(P(s^2|s^2, f)\) is the fiducial distribution of \(\sigma^2\) deduced by assuming \(s^2\) is distributed so that \((s^2/\sigma^2)\) has a \(\chi^2\) density with \(f\) degrees of freedom, and \(K\) is the normalizing constant

\[
K = \int_0^{\infty} \int_0^{\infty} P(s^2_f|s^2_{\tau_f}, q_f)P(s^2|s^2_{\tau}, f) d\sigma^2_f d\sigma^2.
\]

The loss model is defined as the sum of the losses associated with the decision selected for each pair of means. Then for reasons of symmetry the same loss function is assumed for every pair of means. The common loss function written for means \((\mu_1, \mu_2)\) is

\[
L(d_{12}: \theta) = \begin{cases} k_1|\delta|, & \delta \leq 0, \\ 0, & \delta > 0, \end{cases} \quad \quad L(d_{12}: \theta) = \begin{cases} k_2\delta, & \delta \leq 0, \\ 0, & \delta > 0, \end{cases}
\]

in which \(\delta = \mu_1 - \mu_2\) and \(k_1\) and \(k_2\) are positive constants such that \(k_1 \gg k_2\).
2. Simplification of the risk equation

This section has two purposes. The first objective is to define the Bayes solution (with respect to the foregoing model) for selecting either decision \( d^+_{i_1} \) or decision \( d^0_{i_2} \) for means \((\mu_1, \mu_2)\). The second objective is to simplify the risk equation that is used to define the Bayes solution. To meet those aims our first step is to prove the following lemma:

**Lemma 2.1.** The Bayes rule for selecting one of the decisions (1.1) for means \((\mu_1, \mu_2)\) is

\[
\begin{align*}
&\text{make decision } d^+_{i_1} \text{ if } r(z) > k, \\
&\text{make decision } d^0_{i_2} \text{ if } r(z) \leq k,
\end{align*}
\]

where \( k = k_1/k_2 \) and

\[
r(z) = \frac{I^+(z)}{I^-(z)},
\]

in which \( I_+^* \) is the integral

\[
I_+^*(z) = \int_{\Omega^+} |\delta| f(z|\theta) \lambda(\theta) d\theta, \quad * = +, -, 
\]

\( \Omega^+ = \{ \theta : \delta > 0 \}, \ \Omega^- = \{ \theta : \delta \leq 0 \}, \) and \( f(z|\theta) \) and \( \lambda(\theta) \) are defined by (1.2) and (1.3), respectively.

**Proof.** Using (1.2), (1.3) and (1.4), the Bayes risk is minimized by making decision \( d^+_{i_1} \) when \( g(z) < 0 \) and by making decision \( d^0_{i_2} \) when \( g(z) \geq 0 \) where

\[
g(z) = \int [L(d_{i_1}^+ : \theta) - L(d_{i_2}^0 : \theta)] f(z|\theta) \lambda(\theta) d\theta.
\]

Substituting for \( L(d_{i_1}^+ : \theta) \) and \( L(d_{i_2}^0 : \theta) \) from (1.4), we find \( g(z) < 0 \), if, and only if, \( r(z) > k \). That completes the proof of the lemma.

To begin simplifying the critical equation

\[
r(z) = k
\]

apply Fubini's theorem to interchange the order of integration in \( I^+_1 \) and \( I^-_1 \) from \( \sigma^2_1, \gamma_1, \cdots, \gamma_{n-1}, \sigma^2_1 \) to \( \gamma_2, \cdots, \gamma_{n-1}, \gamma_1, \sigma^2_1, \sigma^2_1 \). Then the integrations in (2.4) with respect to \( \gamma_2, \gamma_3, \cdots, \gamma_{n-1} \) are performed by evaluating the product of the integrals

\[
W(y_i) = \int_{-\infty}^{\infty} \exp \left\{ -\frac{1}{2} \left[ \frac{r}{\sigma^2_i} (y_i - \gamma_i)^2 + \frac{\gamma_i^2}{\sigma^2_i} \right] \right\} d\gamma_i, \quad i = 2, 3, \cdots, n-1.
\]
By completing the square and letting \( \sigma_r^2 = r \sigma_e^2 + \sigma_t^2 \), we have

\[
\prod_{i=1}^{n-1} W(y_i) = \left[ -\frac{2 \pi r \sigma_r^2}{\sigma_e^2 (\sigma_r^2 - \sigma_e^2)} \right]^{-(n+1)/2} \exp \left\{ -r \sum_{i=1}^{n-1} \frac{y_i^2}{2 \sigma_r^2} \right\}.
\]

At this point in the evaluation of the integrals involved in (2.4), the solution comes to depend on the data through the difference \( \sqrt{2} y_i (=\bar{x}_i - \bar{x}_2) \), the among treatment variance estimator

\[
s_{rE}^2 = r \sum_{i=1}^{n-1} \frac{y_i^2}{(n-1)},
\]

and the error variance estimator \( s_e^2 \). Then by transforming from \( \eta_i \), \( \sigma_r^2 \), and \( \sigma_e^2 \) to

\[
r = \sqrt{\frac{r \eta_i}{\sigma_e^2}}, \quad \Phi = \frac{\sigma_r^2}{\sigma_e^2}, \quad u^2 = \frac{s_e^2}{\sigma_e^2}
\]

and defining the "pooled" estimates of \( \sigma_r^2 \) and \( \sigma_e^2 \)

\[
s_r^2 = \frac{q_r s_r^2 + (n-1) s_{rE}^2}{q}
\]

\[
s_e^2 = \frac{f_r s_r^2 + f_{rE} s_{rE}^2}{f}
\]

where \( q = q_r + (n-1) \) and \( f = f_r + f_{rE} \), the solution of the critical equation (2.4) depends on the data, \( z \), through the two statistics

\[
t = \frac{\bar{x}_i - \bar{x}_2}{s_d},
\]

\[
F = \frac{s_r^2}{s_e^2},
\]

in which \( s_d^2 = 2 s_t^2 / r \).

After the foregoing indicated integrations and transformations are performed in both \( I_1^+ \) and \( I_1^- \), the critical equation, (2.4), reduces to

\[
\frac{I_1^+(t|F, q, f)}{I_1^-(t|F, q, f)} = k
\]

where

\[
I_* (t|F, q, f) = \int_{1}^{\infty} \int_{0}^{\infty} |\tau| (\Phi - 1)^{-1/2} \Phi^{-(q+1)/2} e^{f - \Phi} u^2 \exp \left\{ - \frac{1}{2} u^2 \left[ A \left( \frac{\tau}{u}, \Phi, t, F \right) \right] \right\} du d\tau d\Phi
\]

in which \( * = +, - \), \( \tau^+ = \{ \tau | 0 < \tau < \infty \} \), \( \tau^- = \{ \tau | -\infty < \tau \leq 0 \} \), and
\[ A(w, x, y, z) = \left\{ y \left[ \frac{x - 1}{x} \right]^{1/2} - w \left[ \frac{x}{x - 1} \right]^{1/2} \right\} + f + \frac{qz}{x}. \]

Since \( I_+^* \) and \( I_-^* \) are further reduced by identical steps, we indicate in detail only the reduction steps for \( I_+^* \) and state the analogous results in \( I_-^* \).

Before integrating with respect to \( u^i \), a change of variable from \( \tau \) to

\[ \gamma = \left\{ \frac{f + q}{f + qF/\Phi} \right\}^{1/2} \left\{ \frac{\tau}{u} \left[ \frac{\Phi}{\Phi - 1} \right]^{1/2} - t \left[ \frac{\Phi - 1}{\Phi} \right]^{1/2} \right\} \]

is made. The integration with respect to \( u^i \) then gives

\[ I_+^*(t|F, q, f) = \int_1^\infty (\Phi - 1)^{1/2} \Phi^{-(q + 1)/2} \left\{ f + \frac{qF}{\Phi} \right\}^{-(f + 1)/2} \]

\[ \times \int_{-1, \beta(\Phi)}^\infty \gamma + t \cdot \beta(\Phi) \left( 1 + \frac{\tau^2}{f'} \right)^{-(f' + 1)/2} d\tau \, d\Phi \]

where \( I_+^*(t|F, q, f) \propto I_+^*(t|F, q, f) \) and

\[ f' = f + q, \]

\[ \beta(\Phi) = \left\{ \frac{f'(\Phi - 1)}{f\Phi + qF} \right\}^{1/2}. \]

Let \( h(z|f') \) denote the density of a \( t \) variable with \( f' \) degrees of freedom, and let \( H(z|f') \) denote the cumulative distribution of the same \( t \) variable. Then the integration with respect to \( \gamma \) produces

\[ I_+^*(t|F, q, f) = \int_1^\infty (\Phi - 1)^{1/2} G(\Phi) M^+(t; \beta(\Phi)|f') d\Phi \]

where \( I_+^*(t|F, q, f) \propto I_+^*(t|F, q, f) \), \( G(\Phi) \) is similar to an \( F \) density with \( q \) and \( f \) degrees of freedom and defined by

\[ G(\Phi) = \Phi^{-(q + 1)/2} \left\{ f + \frac{qF}{\Phi} \right\}^{-(f + 1)/2}, \]

and \( M^+ \) is defined by

\[ M^+(z|f') = \left\{ \frac{f'}{f' - 1} \right\} \left( 1 + \frac{\tau^2}{f'} \right) h(z|f') + zH(z|f'). \]

The same sequence of steps will yield \( I_-^*(t|F, q, f) \propto I_-^*(t|F, q, f) \) where the constants of proportionality are the same for \( I_-^* \) and \( I_+^* \). Thus, the critical equation is reduced to the ratio of two single integrals and expressed by
\[ \frac{I^+_i(t|F, q, f)}{I^-_i(t|F, q, f)} = k \]

in which \( M^{-}(z|f') = M^{+}(-z|f') \).

Differentiation of the left member of equation (2.14) with respect to \( t \) shows that the ratio is a monotonically increasing function of \( t \). Thus, if \( t_c \) is the solution of the critical equation (2.14) for fixed values of \( k, F, q, \) and \( f \), then

\[ \frac{I^+_i(t_c|F, q, f)}{I^-_i(t_c|F, q, f)} = k \text{ and } \frac{I^+_i(t|F, q, f)}{I^-_i(t|F, q, f)} > k \text{ if, and only if, } t > t_c. \]

Therefore, the Bayes rule can be expressed as

\[ \text{make decision } d^+_i \text{ if } t > t_c, \]

\[ \text{make decision } d^-_i \text{ if } t \leq t_c, \]

where \( t \) is defined by (2.7) and \( t_c \) is the solution of (2.14) for given values of \( k, F, q, \) and \( f \).

Now that the Bayes rule can be expressed in terms of the solution to Equation (2.14), the next step is to solve that equation.

3. General recursive solution of the critical equation

This section is used to derive a basic recursive method to generate integrals that are proportional to the integrals \( I^+_i \) and \( I^-_i \) in the critical equation (2.14). A specialization of this recursion formula is used in Section 4 to solve for \( t \) in the equation

\[ \frac{I^+_i(t|F, q, f)}{I^-_i(t|F, q, f)} = k \]

for each fixed set of values \( F', q, f \) and \( k \).

The first step in the development is to define a transformation from \( \Phi \) to \( \phi \) by

\[ \cos^2 \phi = \frac{qF}{f\Phi + qF} \]

and put (for notational convenience only)

\[ \sin \theta = \frac{[1 - \cos^2 \phi/cos^2 \phi_o]^{1/2} t}{[f + (1 - \cos^2 \phi/cos^2 \phi_o) t^2]^{1/2}} \]

in which

\[ \cos \phi_o = \left[ \frac{qF}{f + qF} \right]^{1/2}. \]

The critical equation is then given by

\[ \frac{I^+_i(q - 1, f - 3, -2, 1, f' - 2)}{I^-_i(q - 1, f - 3, -2, 1, f' - 2)} = k \]
where, for \( * = + \) or \(-\)

\[
I^*(m, n, p, w, r) = \int_{\phi_0}^{\pi/2} \cos^m \phi \sin^p \phi \cos^w \theta \sin^w \theta g^*(\theta | r) d\phi,
\]

\[
g^*(\theta | r) = \frac{2^{r/2} \Gamma((r+2)/2)}{(r+2)^{1/2} \Gamma((r+1)/2)} \cos \theta M^*[(r+2)^{1/2} \tan \theta | r+2],
\]

in which \( M^* \) is the function defined by (2.13).

To develop a recursive formula to generate \( I^*(m, n, p, w, r) \), we use the familiar recursive formula to evaluate \( \int \cos^x x \, dx \) to obtain

\[
g^*(\theta | r) = \frac{r}{r-1} g^*(\theta | r-2) - \frac{\cos^r \theta}{r-1},
\]

for \( r = 2, 3, \ldots \) and for \( * = + \) or \(-\). The initial values for the recursion given in (3.6) are

\[
g^+.(\theta | 0) = 1 \pm \sin \theta,
\]

\[
g^-.(\theta | 1) = \cos \theta \pm \left( \frac{\pi}{2} \pm \theta \right) \sin \theta.
\]

Using the result (3.6) along with a method patterned after the standard recursive formula for evaluation \( \int \sin^x x \cos^m x \, dx \), we prove the following theorem.

**Theorem 3.1 (Basic Recursion Theorem).** If \( I^* \), for \( * = + \) or \(-\), is the integral defined in (3.4), then

\[
I^*(m, n, -2, 1, r) = A_0 B^*(m-1, n-1, -4, 3, r) + A_1 I^*(m, n-2, -2, 1, r) + A_2 I^*(m-2, n, -2, 1, r) + \frac{1}{r} J(m, n, r, 1),
\]

where \( S^2 = t^2/(f + t^2), \ C^2 = 1 - S^2, \)

\[
D = \frac{f + qF}{qF}, \ A_0 = \frac{C^2}{rS^2D}, \ A_1 = (n-1) \frac{D-1}{rD}, \ A_2 = \frac{m-1}{rD},
\]

\[
J(m, n, p, w) = \int_{\phi_0}^{\pi/2} \cos^m \phi \sin^p \phi \cos^w \theta \sin^w \theta \, d\phi,
\]

and

\[
B^*(m, n, p, w, r) = \cos^m \phi \sin^p \phi \cos^w \theta \sin^w \theta g^*(\theta | r) \bigg|_{\phi = \phi_0}^{\pi/2}.
\]

**Proof.** To establish (3.8) we put
\[ I^*(m, n, p, w, r) = \int_{-\pi}^{\pi} u \, dv \]

where
\[ u = \frac{C^2}{S^2 D} (\cos \phi)^{m-1} (\sin \phi)^{n-1} (\cos \theta)^{p-1} (\sin \theta)^{w-1} g^*(\theta | r) , \]
\[ dv = \frac{S^2 D}{C^2} \cos \phi \sin \phi \cos^3 \theta \, d\phi . \]

From (3.2) we have
\[ \frac{d\theta}{d\phi} = \frac{S^2 D}{C^2} \left\{ \frac{\cos \phi \sin \phi \cos^3 \theta}{\sin \theta} \right\} . \]

We then use (3.10) and the chain rule of differentiation to determine \( du \) and \( v = \int \sin \theta \, d\theta = -\cos \theta \). Thus, for all choices of \( m, n, p, w, \) and \( r \), the integration by parts formula gives
\[ (p-2)I^*(m, n, p, w, r) \]
\[ = -\frac{C^2}{S^2 D} B^*(m-1, n-1, p-2, w, r) \]
\[ + (1+w)I^*(m, n, p+2, w-2, r) - J(m, n, p+r+2, w-2) \]
\[ + \frac{C^2(n-1)}{S^2 D} I^*(m, n-2, p-2, w, r) \]
\[ + \frac{C^2(m-1)}{S^2 D} I^*(m-2, n, p-2, w, r) . \]

To simplify (3.11), we first use the identity \( \sin^2 x = 1 - \cos^2 x \) to write
\[ I^*(a, b, c, d, e) = I^*(a, b, c, d-2, e) - I^*(a, b, c+2, d-2, e) . \]

We then use (3.2) to deduce
\[ 1 - S^2 D \cos^2 \phi = \frac{C^2}{\cos^2 \theta} . \]

Then we use (3.13) to write
\[ I^*(a, b, c, d, e) = \frac{I^*(a, b, c+2, d, e) - S^2 DI^*(a+2, b, c+2, d, e)}{C^2} , \]
\[ I^*(a, b, c, d, e) = \frac{1 - S^2 D}{C^2} I^*(a, b, c+2, d, e) \]
\[ - \frac{S^2 D}{C^2} I^*(a, b+2, c+2, d, e) . \]
Using (3.12) and (3.14) and putting \( w=3 \) and \( p=-2 \) reduces (3.11) to (3.8). That completes the proof.

The next objective is to specialize the basic recursive relationship (3.8) to generate the integrals \( I^*(q-1, f-3, -2, -1, f'-2) \) for \( * = + \) or \( - \) and fixed values of \( q, f, \) and \( f'=f+q \).

4. Specific recursive solutions of the critical equation

This section gives a method to determine the value of \( t \), say \( t_c \), which satisfies the critical equation (2.14) for any specified set of values for \( (k, F, q, f) \) in these cases:

Case 1: \( F<\infty, q \) is an even integer, and \( f \) is an even integer.
Case 2: \( F<\infty, q=\infty \), and \( f \) is an even integer.
Case 3: \( F=\infty, q \) is an even integer, and \( f \) is an even integer.

Those three cases are discussed in Sections 4.2, 4.3, and 4.4, respectively.

4.1 Refining the basic recursion formula

In our recursive scheme with Equation (3.8), \( m \) is an index to be terminated at \( q-1 \), \( n \) is an index to be terminated at \( f-3 \), and \( r \) is an index to be terminated at \( f'-2 \). But to satisfy the constraint \( f'=f+q \), we require that \( r=m+n+2 \). Thus, we simplify the notation of the previous section as follows:

\[
J(m, n) = J(m, n, r, 1), \quad \text{for } r=m+n+2,
\]

\[
I^*(m, n) = I^*(m, n, -2, 1, r), \quad \text{for } r=m+n+2,
\]

\[
B^*_n = B^*(0, n, -4, 3, n+4).
\]

Further, from the definition of \( B^*(\ ) \) in Theorem 3.1, it follows that

\[
B^*(m, n, -4, 3, m+n+4) = \begin{cases} 
\frac{S^3}{C^4} g^*_{n+4}, & \text{for } m=0 \\
0, & \text{for } m>0,
\end{cases}
\]

where

\[
g^*_z = g^*(\theta | r) \bigg|_{r=\sin^{-1}(S)}
\]

and \( C \) and \( S \) are defined for Theorem 3.1. Also, it follows directly from (3.6) and (3.7) that
\[ g^\pm_r = \frac{r g^{\pm}_{r-1} - C^r}{r - 1}, \]
\[ g^\pm = 1 \pm S, \]
\[ g^\pm = C + S \left[ \tan^{-1} \left( \frac{t^\pm}{f} \right) \pm \left( \frac{\pi}{2} \right) \right]. \]

Then by arguments similar to those used in proving Theorem 3.1, it can be shown that
\[ J(m, n) = \begin{cases} \frac{C^r - S - (n-1)(D-1)J(1, n-2)}{(n+2)D}, & \text{for } m = 1, \\ \frac{(n-1)(D-1)J(m, n-2) + (m-1)J(m-2, n)}{(r-1)D}, & \text{for } m > 1, \end{cases} \]

where \(C, S, \text{ and } D\) are as defined for Theorem 3.1.

By using the definitions in (4.1) and the results in (4.2), (4.3), (4.4) and (4.5) in the recursion (3.8), we can write
\[ I^*(m, n) = \begin{cases} \frac{(S/C^r)g^{\pm}_{n+1} + (n-1)(D-1)I^*(1, n-2)}{(n+2)D}, & \text{for } m = 1, \\ \frac{(n-1)(D-1)I^*(m, n-2) + (m-1)I^*(m-2, n)}{(r-1)D}, & \text{for } m > 1, \end{cases} \]

for \(\ast = + \) or \(-\), \(r = n + m + 2\), and where \(S, C, \text{ and } D\) are previously defined.

The recursions (4.6) are not precise enough to avoid difficulties in round off error on a computer. Therefore, one final refinement is made in the recursive method to generate the ratio of the integrals in Equation (3.3). The result is stated in the following theorem:

**Theorem 4.1.** Let
\[ S^2 = \frac{t^2}{f + t^2}, \quad C^2 = 1 - S^2, \]
\[ D = \frac{f + qF}{qF}, \quad E = \frac{f}{f + qF}, \]
\[ G^\pm = \frac{2[(n-1)/2]! g^\pm}{\pi^{1/2}((n-2)/2)!}, \]
\[ L^*(m, n) = \frac{2(m+n+1)C^2 D^{(m+1)/2}[(m+n-1)/2]!}{\pi^{1/2}S[(m-1)/2]![(n-1)/2]!} I^*(m, n). \]
Then

\[
L^\pm(m, n) = \begin{cases} 
G^\pm_i, & \text{for } n=1 \text{ and } m \geq 1, \\
G^\pm_{i+1} + E \cdot L^\pm(1, n-2), & \text{for } m=1 \text{ and } n>1, \\
L^\pm(m-2, n) + E \cdot L^\pm(m, n-2), & \text{for } m>1 \text{ and } n>1,
\end{cases}
\]

where

\[
G^\pm_i = \frac{2\{C + S[\tan^{-1}(t^i/f) \pm (\pi/2)]\}}{\pi}, \\
G^\pm_i = (1 \pm S)^i,
\]

\[
G^\pm_n = n \frac{G^\pm_{n-2}}{n-2} \frac{C^n[(n-3)/2]!}{\pi^{(n-2)/2}[(n-2)/2]!}, \quad \text{for } n>2.
\]

**Proof.** The results in (4.8) are immediate by using the definition (4.7) and the recursion (4.6) while (4.9) follows directly from the definition of \(G^\pm_n\) and (4.4).

4.2 **Solution for Case 1 \((F < \infty, q \text{ even, and } f \text{ even})**

In this section we outline an iterative method that uses recursions (4.8) and (4.9) to determine the value of \(t\), say \(t_c\), which satisfies Equation (3.3) for a specific set of values \((k, F, q, f)\) where \(F < \infty, q\) is an even positive integer, and \(f\) is an even positive integer.

We note that finding \(t_c\), which satisfies the critical equation in forms (2.4), (2.14), and (3.3) for given values of \((k, F, q, f)\) is equivalent to finding \(t_c\), which satisfies

\[
\frac{L^+(q-1, f-3)}{L^-(q-1, f-3)} = k
\]

for the same values of \((k, F, q, f)\). Thus we use the recursions in (4.8) for odd values of both \(m\) and \(n\) with termination points \((q-1)\) and \((f-3)\), respectively. By simultaneously using Equation (4.9) to generate the necessary \(G^\pm_n\) values and Equation (4.8) to generate \(L^\pm(q-1, f-3)\) we obtain an iterative method to solve (4.10). To illustrate the method, we suppose

\[
k = 100, \quad F = 4, \quad q = 6, \quad f = 10,
\]

and list the iteration steps.

1. Let \(t_i\) be a first guess at the solution to (4.10) for the arguments given in (4.11).
2. Use (4.7) to obtain \(S, C, D,\) and \(E\) from \(t_i, F, q,\) and \(f\).
3. Use (4.9) to generate \(G^\pm_r\), for \(r = 2, 4, 6, 8\) and \(* = +, -\).
4. Use (4.8) to generate
(i) \( L^*(m, 1) = 1, 3, 5 \) for \( * = +, - \).

(ii) \( L^*(1, n), \ L^*(3, n), \ L^*(5, n), \ n = 3, 5, 7 \) for \( * = +, - \).

5. Calculate
\[
k(t_i) = L^+(5, 7)/L^-(5, 7).
\]

6. Compute the derivatives \( L^*(5, 7) \) of \( L^*(5, 7) \) with respect to \( t \) for \( * = +, - \). Those calculations can be completely in conjunction with the corresponding calculations of \( L^*(5, 7) \) by differentiating the recursions which generate \( L^*(m, n) \) and \( G^*_r \) to obtain recursions which generate \( L^*(m, n) \) and \( G^*_r \).

7. Compute the derivative \( k'(t_i) \) of the ratio \( k(t_i) \) where
\[
k'(t_i) = [L^-(5, 7)L^+(5, 7) - L^+(5, 7)L^-(5, 7)]/[L^-(5, 7)]^2.
\]

8. Obtain a second approximation of \( t \), using
\[
t_2 = t_1 + (k - k(t_1))/k'(t_1).
\]

9. Repeat steps 2 through 8 replacing \( t_i \) by \( t_2 \) and obtain a third approximation \( t_3 \) for \( t \). Iterate to convergence.

The foregoing method was used along with appropriate interpolation formulae to compute a set of critical \( t \) value tables for selected values of \( (k, F, q, f) \). The tables in Waller and Duncan [4] contained an error, but a corrected set of tables are available in Waller and Duncan [5]. An algorithm (ASA FORTRAN) for calculating the critical \( t \)-values, \( t_c \), is available on request.

4.3 Solution for Case 2 \((F < \infty, q \rightarrow \infty, f \text{ even})\)

Case 2 is identical to Case 1 except that \( q \) is no longer finite. Rather than proceeding directly to the limit of (4.8) as \( q \rightarrow \infty \), it is convenient to prove this theorem:

THEOREM 4.2. If \( q \) is an even integer \((\geq 2)\) and if \( f \) is an even integer \((\geq 4)\), then

\[
L^*(q-1, f-3) = \sum_{i=0}^{(f-6)/2} E^i(q-2)/i G^*_r - 2t, \quad * = +, -
\]

where \( E^*, L^* \), and \( G^* \) are defined in (4.7), (4.8) and (4.9).

PROOF. (i) If \( f = 4 \), then by (4.8) \( L^*(q-1, 1) = G^*_r \) for all values of \( q \) and (4.12) holds.

(ii) If \( q = 2 \), a proof by induction yields (4.12). First, part (i) shows that \( L^*(1, 1) = G^*_r \). Second, from the induction assumption that

\[
L^*(1, f-5) = \sum_{i=0}^{(f-6)/2} E^iG^*_r - 2t
\]

and (4.8) it follows that (4.12) holds.

(iii) Finally, that (4.12) holds for \( q > 2 \) and \( f > 4 \) follows by substituting the inductive hypotheses
\[ L^*(q-3, f -3) = \sum_{i=0}^{(f-4)/3} E^i \left( \frac{(q-4)/2 + i}{i} \right) G^*_f \]

\[ L^*(q-1, f -5) = \sum_{i=0}^{(f-6)/3} E^i \left( \frac{(q-2)/2 + i}{i} \right) G^*_f \]

into (4.8).

An immediate consequence of Theorem 4.2 is as follows:

**Theorem 4.3.** If \( f \) is an even integer, then

\[ L^*(\infty, f -3) = \sum_{i=0}^{(f-4)/3} \left( \frac{f}{2F} \right)^i \frac{1}{i!} G^*_f, \quad \text{for } * = +, - . \]

**Proof.** In view of (4.12), we need only show that

\[ \lim_{q \to -\infty} \left( \frac{(q-2)/2 + i}{i} \right) E^i = \left( \frac{f}{2F} \right)^i \frac{1}{i!} \]

to establish (4.13). From the definition of \( E \) in (4.7) and \( \binom{a}{b} \) we have

\[ \lim_{q \to -\infty} \left( \frac{(q-2)/2 + i}{i} \right) E^i = \left( \frac{f}{2F} \right)^i \frac{1}{i!} \lim_{q \to -\infty} \prod_{j=1}^{i} \frac{1+2(j-1)/q}{1+1/q} = \left( \frac{f}{2F} \right)^i \frac{1}{i!} . \]

The critical \( t \) values for Case 2 can now be found by using (4.13) in an iterative method similar to that given in Section 4.2 for Case 1.

4.4 Solution for Case 3 (\( F \to \infty, q \text{ even}, f \text{ even} \))

To obtain the desired integrals for \( F = \infty, q \) an even integer, and \( f \) an even integer, we use (4.12) to prove this theorem:

**Theorem 4.4.** If \( q \) is an even integer (\( \geq 2 \)) and \( f \) is an even integer (\( \geq 4 \)), then

\[ \lim_{F \to -\infty} L^*(q-1, f -3) = G^*_f, \quad \text{for } * = +, - . \]

**Remark.** When \( F = \infty \), we obtain the same critical value for all values of \( q \).

**Proof.** Since \( G^*_f \) is not a function of \( F \), it follows from (4.12) that

\[ \lim_{F \to -\infty} L^*(q-1, f -3) = \sum_{i=1}^{(f-4)/3} G^*_f \left( \frac{(q-2)/2 + i}{i} \right) \lim_{F \to -\infty} E^i . \]

Now by (4.7) \( E = f/(f + qF) \). Therefore \( \lim_{F \to -\infty} E^i = 0 \), for all finite values of \( i \), which establishes (4.14).

Here again an iterative method similar to that outlined for Case 1 can be used to calculate the critical \( t \) value for any given pair of
values for \( k \) and \( f \).

That concludes the solutions for the three cases defined at the beginning of this section. The somewhat more cumbersome recursive techniques to obtain solutions to some remaining cases are discussed in the next two sections.

5. Case 4: The two treatment experiment

The solution for the two-treatment experiment is developed in this section. In this special case \((q=1)\), the quantities \( F \) and \( t^q \) (see (2.7)) are identical. Setting \( q=1 \) and \( F=t^2 \) simplifies many of the quantities defined in Theorem 3.1. The following lemmas summarize the results for \( q=1 \) and lead to the recursion formula for the integrals \( I^x(0, n) \) given in Theorem 5.1.

**Lemma 5.1.** If \( q=1 \), then

\[(i) \quad D = \frac{1}{S^2}, \]
\[(ii) \quad E = C^2, \]
\[(iii) \quad \sin \phi = \frac{C}{\cos \theta}, \]
\[(iv) \quad \cos \phi = \frac{(\cos^2 \theta - C^2)^{1/2}}{\cos \theta}, \]
\[(v) \quad d\phi = \frac{C \sin \theta \, d\theta}{(\cos^2 \theta - C^2)^{1/2} \cos \theta}. \]

**Proof.** Using \( F=t^2 \) and \( q=1 \) in the definitions of \( D \) and \( E \) as given (4.7) establishes (i) and (ii). Parts (iii), (iv), and (v) follow directly from (3.12) when \( D \) is replaced by \( 1/S^2 \).

**Lemma 5.2.** If \( q=1 \) and \( J(0, n) \) is as defined for (4.1), then

\[ J(0, n) = \frac{C^{n+1}S^2 \pi}{4}. \]

**Proof.** By definition (see (4.1) and Theorem 3.8)

\[ J(0, n) = \int_{\phi_0}^{\pi/2} \sin^n \phi \cos^{n+2} \theta \sin \theta \, d\phi. \]

Using parts (iii) and (v) of (5.1) to replace \( \sin \phi \) and \( d\phi \) gives

\[ J(0, n) = C^{n+1} \int_{\phi_0}^{\pi/2} \frac{\cos \theta \sin^2 \theta}{(\cos^2 \theta - C^2)^{1/2}} \, d\theta, \]
where $\sin^{2}\theta = S$. Evaluation of (5.3) gives (5.2).

**Lemma 5.3.** If $E$, $D$, $I^{z}(m, n)$ and $J(m, n)$ (see (4.1) and (5.1)), are as previously defined, then

\[(5.4)\quad I^{z}(0, n) = \left[ 1 + \left( \frac{n-2}{n+1} \right) C^{z} \right] I^{z}(0, n-2) - \frac{(n-3) n C^{z}}{n^{2}-1} I^{z}(0, n-4) - \frac{C^{n-1} S^{2} \pi}{2(n^{2}-1)}.\]

**Proof.** Using $m=2$ in (4.6), we obtain

\[(5.5)\quad I^{z}(2, n) = \left( \frac{n-1}{n+3} \right) EI^{z}(2, n-2) + \frac{1}{(n+3)D} I^{z}(0, n).\]

Definition (3.6) and (4.1) imply that

\[(5.6)\quad I^{z}(2, n) = \left( \frac{n+4}{n+3} \right) I^{z}(0, n) - \frac{1}{n+3} J(0, n) - I^{z}(0, n+2).\]

Likewise,

\[(5.7)\quad I^{z}(2, n-2) = \left( \frac{n+2}{n+1} \right) I^{z}(0, n-2) - \left( \frac{1}{n+1} \right) J(0, n-2) - I^{z}(0, n).\]

By substituting (5.6) and (5.7) into (5.5) and by replacing $(n+2)$ by $n$ we obtain

\[(5.8)\quad I^{z}(0, n) = \left[ \left( \frac{n-3}{n+1} \right) E + \frac{1}{(n+1)D} + \left( \frac{n+2}{n+1} \right) \right] I^{z}(0, n-2) - \frac{(n-3) n E I^{z}(0, n-4)}{n^{2}-1} - \left( \frac{1}{n+1} \right) J(0, n-2) + \frac{(n-3) E}{n^{2}-1} J(0, n-4).\]

The use of (5.2) and parts (i) and (ii) of (5.1) establishes (5.4).

The foregoing lemmas and definitions are used to state and prove the following theorem which can be used to obtain critical $t$-values for a two-treatment experiment.

**Theorem 5.1.** Let

\[(5.9)\quad L^{z}(0, n) = \frac{2C^{z}(n+1)}{\pi S^{2}} I^{z}(0, n).\]

If $q=1$, then

\[(5.10)\quad L^{z}(0, n) = \frac{(n+1)+(n-2)C^{z}}{n-1} L^{z}(0, n-2) - \frac{n C^{z}}{n-1} L^{z}(0, n-4)\]
\[-\frac{C^{n+1}}{n-1}, \quad \text{for } n \geq 4.\]

**Proof.** Multiplying (5.4) by \(2C(n+1)/\pi S^2\) and replacing \(I^z(0, n-2)\) and \(I^z(0, n-4)\) by \([\pi S^3/2C^2(n-1)]L^z(0, n-2)\) and \([\pi S^3/2C^2(n-3)]L^z(0, n-4)\), respectively, gives (5.10).

The following quantities are needed to initialize the recursion (5.10) and can be obtained by integration:

\[
L^z(0, 0) = \frac{1 - 2C^3 + C^3}{\sqrt{S^2}} \pm \frac{2}{\pi S^3} \left[ CS + (S^2 - C^2) \tan^{-1} \left( \frac{S}{C} \right) \right],
\]

\[
L^z(0, 1) = (1 \pm S)^2,
\]

\[
L^z(0, 2) = \frac{1}{S^2} \left[ 3 - 4C^2 + C^3 \right]
\]

\[
\pm \frac{2}{\pi S^3} \left[ CS(1 + 2S^2) + (3 - 4C^3) \tan^{-1} \left( \frac{S}{C} \right) \right],
\]

\[
L^z(0, 3) = \frac{2[2 + 2S^2 + S^4C^3] \pm 2S(4 + C^3)}{2}.
\]

The recursion in (5.10) and the starting values in (5.11) can be used in an iterative scheme (similar to that presented in Section 4.2) to determine that value of \(t\), say \(t_0\), which satisfies the equation

\[
\frac{L^z(0, f - 3)}{L^z(0, f - 3)} = k
\]

for each given pair of values \((k, f)\) such that \(f \geq 3\).

That concludes the development of the solution for the two-treatment experiment.

6. Discussion of other cases

Three remaining cases of interest for \(F < \infty\) can be identified according to the possible values of \(q\) and \(f\) as follows:

- **Case 5:** \(q\) and \(f\) are both odd integers \(\geq 4\).
- **Case 6:** \(q\) is an even integer \(\geq 2\), and \(f\) is an odd integer \(\geq 3\).
- **Case 7:** \(q\) is an odd integer \(\geq 3\), and \(f\) is an odd integer \(\geq 3\).

To use the recursive techniques in Sections 3 and 4 to solve the three cases above, recursions that generate the quantities \(L^z(0, n)\) and \(L^z(m, 0)\) are needed to initiate the recursive system given in (4.8). Those recursions can be derived with the method used to prove Theo-
Theorem 3.1 along the results and definitions in Theorem 4.1. The derivations are similar to those used in Section 5 to derive a recursive method for generating $L^2(0, n)$ when $q=1$. However, the recursions and their initial values require evaluation of certain elliptic integrals, which tends to make the development tedious and bulky. Therefore, a detailed treatment of the recursive method for the cases identified above will be presented after further research directed to simplifying the technique is completed. In the meantime access to the development in its current state is available on microfilm in the thesis by Waller [3].

7. The Bayes rule

The foregoing development completes the derivation of the Bayes rule for the symmetric multiple comparisons problem presented and discussed by Waller and Duncan [4]. In this section we state that Bayes rule. First, we state the rule for those cases where $q>1$. Second, the rule for the case when $q=1$ is given.

**Bayes rule ($q>1$):** Let $t^* = t(k, F, q, f)$ be that value of $t$ that satisfies Equation (2.14) (or equivalently (4.10)) for a specified vector $(k, F, q, f)$. Let $t_{ij} = (x_i - x_j)/s_d$ where $s_d$ is defined for (2.7). Then the Bayes rule for the symmetric multiple comparisons problem is the simultaneous application of this rule to all $n(n-1)/2$ pairs of treatment means:

- If $t_{ij} > t_c$, conclude $\mu_i > \mu_j$.
- If $|t_{ij}| < t_c$, conclude $\mu_i$ is unranked relative to $\mu_j$.
- If $t_{ij} < -t_c$, conclude $\mu_i < \mu_j$.

**Bayes rule ($q=1$):** Let $t^*$ be that value of $t$ that satisfies Equation (5.1) for a specified vector $(k, f)$. Let $t_{ij} = (x_i - x_j)/s_d$ where $s_d$ is defined for (2.7). The Bayes rule for the symmetric multiple comparisons problem for means $\mu_1$ and $\mu_2$ is the application of (6.1) with $t_c = t^*_i$, $i=1$, and $j=2$.

That completes the statement of the Bayes rule for the symmetric multiple comparisons problem.

8. Conclusion

The mathematical derivation of a Bayes rule for the symmetric multiple comparisons problem has been presented in the foregoing sections of this paper. An application method for that Bayes rule and
tables of the critical $t$-values for selected values of $k$, $F$, $q$ and $f$
were presented in Waller and Duncan [4], [5].

There are, however, some open problems remaining that need to
be solved to complete the solution. One open problem is the asym-
ptotic solution for the case when $f \to \infty$ and $q$ is finite. Another re-
sult of interest is refining the recursive technique to obtain a set of
recursions for Cases 5, 6, and 7, which are as precise and efficient for
computer use as those used in Cases 1, 2, 3, and 4. That result would
eliminate the necessity of using interpolation methods to determine the
critical $t$-values for Cases 5, 6, and 7. We note that even though the
available tables values for those cases were determined by interpo-
lation the numbers are accurate to two decimal places. Thus, the ap-
proximations involved are of no practical importance.
