IMPROVED ESTIMATION OF PARAMETER MATRICES
IN A ONE-SAMPLE AND TWO-SAMPLE PROBLEMS

(Received October 19, 1999; revised July 14, 2000)

Abstract. In this paper, the problems of estimating the covariance matrix in a Wishart distribution (refer as one-sample problem) and the scale matrix in a multivariate $F$ distribution (which arise naturally from a two-sample setting) are considered. A new class of estimators which shrink the eigenvalues towards their harmonic mean is proposed. It is shown that the new estimator dominates the best linear estimator under two scale invariant loss functions.

Key words and phrases: Covariance matrix, orthogonally invariant estimator, decision-theoretic estimation, shrinkage estimator, harmonic mean, eigenvalues.

1. Introduction and summary

Suppose that a random $m \times m$ positive definite matrix $S$ has a nonsingular Wishart distribution with unknown covariance matrix $\Sigma$ and $n$ degrees of freedom, i.e., $S \sim W_m(n, \Sigma)$. There has been considerable research in estimating the covariance matrix $\Sigma$ using a decision-theoretic approach. It is shown that substantial improvement (reduction in risks) over the usual unbiased estimator of $\Sigma$ can be obtained, essentially by focusing attention on the problem of estimating the eigenvalues of $\Sigma$ by functions of all the eigenvalues of $\Sigma$. In particular, Stein (1975) considered the class of orthogonally invariant estimators of $\Sigma$ of the form

\begin{equation}
\hat{\Sigma} = H\Phi(Q)H'
\end{equation}

where $S = HQH'$ with $H$ the matrix of normalized eigenvectors ($HH' = H'H = I_m$), $Q = \text{diag}(l_1, \ldots, l_m)$ is the diagonal matrix of eigenvalues of $S$ with $l_1 > \cdots > l_m > 0$ and $\Phi(Q) = \text{diag}(\phi_1(Q), \ldots, \phi_m(Q))$, $\phi_i(Q) \geq 0$ is a real valued function, $i = 1, \ldots, m$. Work along this direction can be found in Haff (1980), Dey and Srinivasan (1985), Lin and Perlman (1985) and Dey (1988). Excellent reviews on this topic can be found in Muirhead (1987) and Pal (1993). However, all the proposed estimators will shrink the eigenvalues towards the origin. In practice, it is more useful and reasonable to shrink the eigenvalues toward some central values.

In this paper, we consider the problem of estimating $\Sigma$ using two scale-invariant loss functions

\begin{equation}
L_1(\Sigma, \hat{\Sigma}) = \text{tr}(\hat{\Sigma}\Sigma^{-1}) - \ln |\hat{\Sigma}\Sigma^{-1}| - m,
\end{equation}

769
and

$$L_2(\Sigma, \hat{\Sigma}) = \text{tr}(\hat{\Sigma}\Sigma^{-1} - I_m)^2.$$  

Haff (1980) shows that for \( c_1 = 1/n \) and \( c_2 = 1/(n+m+1) \), \( c_1 S \) and \( c_2 S \) has the smallest risk among all the scalar multiples of \( S \) under \( L_1 \) and \( L_2 \) loss function respectively. We refer these estimators as the best linear estimators thereafter. We proposed a new estimator of the form

$$\hat{\Sigma}(\alpha) = \alpha c S + (1 - \alpha)\frac{m}{\text{tr} S^{-1}} I_m$$  

where \( 0 \leq \alpha \leq 1 \). \( c \) is a constant appropriately chosen for the two loss functions (1.2) and (1.3), i.e., \( c_1 \) for \( L_1 \) loss function and \( c_2 \) for \( L_2 \) loss function. We prove that \( c_1 S \) and \( c_2 S \) are inadmissible and is dominated by \( \hat{\Sigma}(\alpha) \) in (1.4) for some values of \( \alpha \). Note that for \( \alpha = 1 \), \( \hat{\Sigma}(\alpha) \) corresponds to the linear estimator \( cS \). \( \hat{\Sigma}(\alpha) \) is in the class of orthogonally invariant estimators defined in (1.1) with eigenvalues

$$\phi_i(L) = \alpha cl_i + (1 - \alpha)\bar{l},$$

$$= cl_i - (1 - \alpha)c(l_i - \bar{l}) \quad (i = 1, \ldots, m)$$

where \( \bar{l} = m/\text{tr} S^{-1} \) is the harmonic mean of \( l_1, \ldots, l_m \), the eigenvalues of \( S \).

This estimator is motivated by the fact that the sample eigenvalues of \( S \) usually tend to be much more dispersed than the population eigenvalues of \( \Sigma \) (see Muirhead (1987)), i.e., \( l_1 \) tends to over-estimate the largest population eigenvalue while \( l_m \) tends to under-estimate the smallest population eigenvalue. Intuitively, \( cS \) can be improved by shrinking the sample eigenvalues towards some central value. From equation (1.5), it is easy to see that \( \phi_2(L) \) is obtained by shrinking \( cl_i \), the eigenvalues of \( cS \), towards their harmonic mean \( \bar{c} \). The amount of shrinkage depends on the parameter \( \alpha \) and the distance between \( l_i \) and \( \bar{l} \). \( \alpha \) is the shrinkage parameter ranging from 0 to 1 representing various degrees of shrinkage. Note also that \( \hat{\Sigma}(\alpha) \) in (1.4) preserves the order of the sample eigenvalues \( l_i \). This class of order-preserving orthogonally invariant estimator is well studied by Sheena and Takemura (1992) as it form a complete class.

This idea of shrinking the eigenvalues towards certain central value is not new. It has been used in Friedman (1989) and Leung and Chan (1998) where the arithmetic mean, instead of the harmonic mean, was adopted as the central value. In Fricicman (1989), he used this shrinkage in discriminant analysis, and coined the name ‘regularized discriminant analysis’. In Leung and Chan (1998), they considered the same estimation problem using the squared error loss function. However, this squared error loss function is not scale invariant. We would like to develop similar dominance results for the \( L_1 \) and \( L_2 \) loss functions. If we shrink the eigenvalues towards their sample mean as in Leung and Chan (1998), it is extremely difficult to obtain dominance results. If we use the harmonic mean as the central value, we are able to obtain dominance results as in Sections 2 and 3. Another possible way is to shrink the eigenvalues towards their geometric mean, but this possibility will not be explored in the paper and leave for further study.

Another closely related problem is the estimation of the scale matrix \( \Delta \) in a multivariate \( F \) distribution. This problem has been considered by various authors, namely, Muirhead and Verathaworn (1985), Leung and Muirhead (1988), Dey (1989), Gupta and
Krishnamoorthy (1990), Konno (1991) and Leung (1992). This problem arises naturally from a two-sample setting (see Muirhead and Verathaworn (1985) and Leung and Muirhead (1988)).

Suppose that a random $m \times m$ positive definite matrix $F$ has a multivariate $F$ distribution with degrees of freedom $n_1$ and $n_2$ and scale matrix $\Delta$, i.e., $F \sim F_m(n_1, n_2; \Delta)$. We consider the two invariant loss functions (1.2) and (1.3) (with $\Sigma$ replaced by $\Delta$). Muirhead and Verathaworn (1985) show that $c_3 F$, where

$$ (1.6) \quad c_3 = (n_2 - m - 1)/n_1, $$

is the best among all scalar multiple of $F$ under the $L_1$ loss function when $n_2 > m + 1$. Later on, Leung and Muirhead (1988) show that $c_4 F$, where

$$ (1.7) \quad c_4 = \frac{(n_2 - m)(n_2 - m - 3)}{(n_2 - m - 1)(n_1 + m + 1) + mn_1 + 2}, $$

is the best among all scalar multiples of $F$ under the $L_2$ loss function when $n_2 > m + 3$. Using a similar approach as in the Wishart situation, we propose a new class of orthogonally invariant estimators of the form

$$ (1.8) \quad \hat{\Delta}(\alpha) = \alpha cF + (1 - \alpha)c\frac{m}{\text{tr} F^{-1}} I_m $$

where $0 \leq \alpha \leq 1$.

The present paper is organized as follows: In Section 2, we considered the problem of estimating the covariance matrix $\Sigma$ in a Wishart distribution (one-sample problem) and the scale matrix $\Delta$ in a multivariate $F$ distribution (two-sample problem) under the $L_1$ loss function. We proved that the best linear estimator $c_1 S$ (and $c_3 F$) is inadmissible and is dominated by $\hat{\Sigma}(\alpha)$ in (1.4) (and $\hat{\Delta}(\alpha)$ in (1.8)) for some suitable chosen values of $\alpha$. Similarly in Section 3, we considered the same estimation problem using the $L_2$ loss function. Finally, a simulation study is carried out to study the performance of these new estimators in Section 4.

In Sections 2 and 3, some expectations involved in the risk calculations are very complicated and cannot be expressed in closed forms. However, in order to prove the dominance results, only upper and lower bounds for these expectations are needed. These bounds are formulated as the following lemma and will be used in Sections 2 and 3.

**Lemma 1.** Assume that $m > 1$, $n_1 > m + 1$ and $n_2 > m + 1$. Let $F \sim F_m(n_1, n_2; \Delta)$.

(i) $E[\text{tr}(\Delta^2 F^{-1})] \leq \frac{(n_1 - m - 3)}{n_2 - 4} E[\text{tr} \Delta^2 F^{-1}],$

(ii) $E[\text{tr}(\Delta^2 F^{-1})] \leq \frac{[(n_1 + 2)(n_2 - 2) - 2(m - 1)]}{(n_2 - m - 1)(n_2 - 4)} E[\text{tr} \Delta^2 F^{-1}],$

(iii) $\frac{n_1 - m - 1}{n_2} \leq E[\text{tr} \Delta^{-1} F^{-1}] \leq \frac{n_1 - m + 1}{n_2 - 2}.$

Lemma 1 can be proved by the multivariate $F$ identity (see Muirhead and Verathaworn (1985) and Konno (1988)). The proof of this lemma together with the multivariate $F$ identities are given in the Appendix.
2. Improved estimation of $\Sigma$ and $\Delta$ under $L_1$ loss function

First we consider the problem of estimating the scale matrix $\Delta$ in a multivariate $F$ distribution. Estimation of $\Sigma$ in a Wishart distribution can be considered as a limiting case of the former problem and will be considered later. Let $A \sim W_m(n_1, \Delta)$ and independent of $B \sim W_m(n_2, I)$. Then the random $m \times m$ positive definite matrix $F = A^{1/2}B^{-1}A^{1/2}$ has a multivariate $F$ distribution with degrees of freedom $n_1$ and $n_2$ and scale matrix $\Delta$, i.e., $F \sim F_m(n_1, n_2; \Delta)$. Muirhead and Verathaworn (1985) show that $c_3F$, where $c_3$ is given in (1.6), is the best linear estimator of $\Delta$. The main result in this section is to provide a sufficient condition on $\alpha$ such that $c_3F$ is dominated by $\hat{\Delta}(\alpha)$ defined in (1.8).

**Theorem 2.1.** Assume that $m > 1$, $n_1 > m + 1$ and $n_2 > m + 1$. Applying the loss function (1.2),

\[(2.1) \quad \hat{\Delta}_1(\alpha) = \alpha c_3F + (1 - \alpha)c_3 \frac{m}{\text{tr} F^{-1}} I_m\]

dominates the best linear estimator $c_3F$ provided that

\[(2.2) \quad -q + \frac{\sqrt{q^2 + 8(m - 1)(n_1 + n_2 - m - 1)}}{4(m - 1)(n_1 + n_2 - m - 1)} \leq \alpha < 1,
\]

where $q = mn_1(n_2 - 2)$.

**Proof.** For the loss function in (1.2), it is straightforward to show that the risk difference between $c_3F$ and $\hat{\Delta}_1(\alpha)$ is

\[
G_1(\Delta) = E[L_1(\Delta, c_3F)] - E[L_1(\Delta, \hat{\Delta}_1(\alpha))]
= (1 - \alpha)m \left\{ 1 - c_3E \left[ \frac{\text{tr} \Delta^{-1}}{\text{tr} F^{-1}} \right] \right\} + E \left[ \ln \left| I_m + \frac{(1 - \alpha)m}{\alpha(\text{tr} F^{-1})} F^{-1} \right| \right]
+ m \ln \alpha.
\]

Using the upper bound in (iii) of Lemma 1 and $\ln |I + A| \geq \text{tr} A - (1/2) \text{tr} A^2$ for any positive definite matrix $A$ (see Konno (1991), p. 160), we have

\[
G_1(\Delta) \geq \frac{(1 - \alpha)m(m - 1)(n_1 + n_2 - m - 1)}{n_1(n_2 - 2)} + m \ln \alpha + \frac{(1 - \alpha)m}{\alpha}
+ \frac{(1 - \alpha)^2m^2}{2\alpha^2} E \left[ \frac{\text{tr}(F^{-2})}{(\text{tr} F^{-1})^2} \right].
\]

Note that $\ln \alpha \geq -(1 - \alpha)/\alpha$ and $\text{tr}(F^{-2})/(\text{tr} F^{-1})^2 \leq 1$,

\[(2.3) \quad G_1(\Delta) \geq \frac{(1 - \alpha)m}{2n_1(n_2 - 2)\alpha^2} [2(m - 1)(n_1 + n_2 - m - 1)\alpha^2 + q\alpha - q],\]
where \( q = mn_1(n_2 - 2) \). Note that the term in the square bracket in (2.3) is a quadratic function in \( \alpha \) with the coefficient of \( \alpha^2 \) being positive. The condition (2.2) in Theorem 2.1 ensures that the lower bound for \( G_1(\Delta) \) in (2.3) is non-negative and the proof is completed.

\[ r = \frac{mn_1(n_2 - 2)}{(m - 1)(n_1 + n_2 - m - 1)}. \]

Cartan's solution of this cubic equation (see Merritt (1962), p. 49) is:

\[ \alpha_1 = \sqrt[3]{\frac{r}{2} + \sqrt{\left(\frac{r^2}{4} + \frac{r^3}{27}\right)}} + \sqrt[3]{\frac{r}{2} - \sqrt{\left(\frac{r^2}{4} + \frac{r^3}{27}\right)}}. \]

**Remark 2.** An anonymous referee pointed out that the result in Theorem 2.1 can be generalized easily by considering a new class of estimators

\[ \hat{\Delta}_N(\alpha) = \alpha c_3 F + (1 - \alpha)c_3 g(\vartheta) I_m \]

where \( \vartheta = m / \text{tr} F^{-1} \), and \( g(\vartheta) \) is a bounded positive real valued function of \( \vartheta \) such that \( 0 < k_1 \leq g(\vartheta) \leq k_2 < \infty \), for some constants \( 0 < k_1 \leq k_2 \). With this \( \hat{\Delta}_N(\alpha) \) and similar calculation, one can write the risk difference

\[ G_N(\Delta) = E[L_1(\Delta, c_3 F)] - E[L_1(\Delta, \hat{\Delta}_N(\alpha))] \]

\[ \geq \frac{(1 - \alpha)m}{\alpha^2} \left\{ \left[ 1 - c_3 k_1 \left( \frac{n_1 - m + 1}{n_2 - 2} \right) \right] \alpha^2 + (k_1 - 1)\alpha - \frac{1 - \alpha}{2}mk_2^2 \right\}. \]

The expression in the curly bracket is a quadratic function in \( \alpha \). Therefore, one can establish a similar sufficient condition on \( \alpha \) such that \( G_N(\Delta) > 0 \). However, this condition is rather messy and depends on \( k_1 \) and \( k_2 \). When \( k_1 = k_2 = 1 \), \( \hat{\Delta}_N(\alpha) \) reduces to \( \hat{\Delta}_1(\alpha) \) and \( G_N(\Delta) \) reduces to \( G_1(\Delta) \).

Now we turn to the problem of estimating \( \Sigma \) in a Wishart distribution.

**Theorem 2.2.** Assume that \( m > 1 \) and \( n > m + 1 \). Applying the loss function (1.2),

\[ \hat{\Sigma}_1(\alpha) = \alpha c_1 S + (1 - \alpha)c_1 \frac{m}{\text{tr} S^{-1}} I_m \]
dominates the best linear estimator $c_1 S$ (where $c_1 = 1/n$) provided that

$$
\frac{-nm + \sqrt{n^2 m^2 + 8nm(m - 1)}}{4(m - 1)} \leq \alpha < 1.
$$

**Proof.** Note that in the two-sample situation, $F = A^{1/2} B^{-1} A^{1/2}$ where $A \sim W_m(n_1, \Delta)$ and independent of $B \sim W_m(n_2, I)$. $B$ can be considered as the sum of squares and cross product matrix of $n_2$ independently and identically distributed $m \times 1$ standard normal random vectors. By the strong law of large numbers, $n_2^{-1} B$ converges to $I_m$ or $n_2 F$ converges to $A$ almost surely, as $n_2$ tends to infinity. This becomes the problem of estimating the covariance matrix $\Sigma$ in a Wishart distribution. Furthermore, $n_2 F$ is uniformly integrable so exchange between $\lim_{n_2 \to \infty}$ and expectation is possible. Therefore, the sufficient condition (2.8) in Theorem 2.2 can be obtained by letting $n_2 \to \infty$ in the sufficient condition (2.2) in Theorem 2.1 (with $n_1$ replaced by $n$) and the proof is completed.

**Remark 3.** It is possible to prove Theorem 2.2 by computing the risk difference directly as in Theorem 2.1. However, it is easier to prove the result by letting $n_2 \to \infty$. This technique has also been used in Leung and Chan (1998). The ‘optimal’ value for $\alpha$ (maximizes the risk difference between $c_1 S$ and $\tilde{\Sigma}(\alpha)$) in this one-sample situation is the same as in equation (2.5) except that $r = mn/(m - 1)$. Again this is obtained by letting $n_2 \to \infty$ and $n_1$ is replaced by $n$ in (2.4).

3. Improved estimation of $\Sigma$ and $\Delta$ under $L_2$ loss function

Similar to Section 2, we first consider the problem of estimating $\Delta$ in a multivariate $F$ distribution. The corresponding result for estimating $\Sigma$ in a Wishart distribution can be obtained by letting $n_2 \to \infty$. Leung and Muirhead (1988) show that $c_4 F$, where $c_4$ is given in (1.7), is the best linear estimator of $\Delta$. The main result in this section is to provide a sufficient condition on $\alpha$ such that $c_4 F$ is dominated by $\hat{\Delta}(\alpha)$ defined in (1.8).

**Theorem 3.1.** Assume that $m > 3$,

\begin{align*}
(3.1) & \quad n_1 \geq m + 3 + 12/(m - 3), \\
(3.2) & \quad n_2 \geq \frac{\sqrt{t_1(m + 5) - t_2(m + 2)^2} - 8(t_1 - t_2)[2t_1(m + 1) - mt_2]}{2(t_1 - t_2)} + \frac{t_1(m + 5) - t_2(m + 2)}{2(t_1 - t_2)}, \\
\text{where } & \quad t_1 = (n_1 - m - 1)(n_1 + m + 1), t_2 = (n_1 - m + 1)(n_1 + 2) \text{ and} \\
(3.3) & \quad n_2 \geq \frac{m(m + 1)(n_1 - m + 3) - 4(m - 1)}{(m - 1)(n_1 - m + 2)}.
\end{align*}

Applying the loss function (1.3),
(3.4) \[ \hat{\Delta}_2(\alpha) = \alpha c_4 F + (1 - \alpha)c_4 \frac{m}{\text{tr } F^{-1}} I_m \]

dominates the best linear estimator \( c_4 F \) provided that \( b_1/a_1 \leq \alpha < 1 \) where

(3.5) \[ a_1 = k - \frac{2c_4(n_1 - m + 1)[(n_1 + 2)(n_2 - 2) - 2(m - 1)]}{(n_2 - 2)(n_2 - 4)(n_2 - m - 1)}, \]

(3.6) \[ b_1 = k - 2(n_1 - m - 1)/n_2, \]
\[ k = \frac{n_1}{n_2 - m - 1} + \frac{mc_4(n_1 - m + 1)(n_1 - m + 3)}{(n_2 - 2)(n_2 - 4)}. \]

PROOF. For the loss function in (1.3), it is straightforward to show that the risk difference between \( c_4 F \) and \( \hat{\Delta}_2(\alpha) \) is

\[
G_2(\Delta) = E[L_2(\Delta, c_4 F)] - E[L_2(\Delta, \hat{\Delta}_2(\alpha))] = (1 - \alpha)mc_4 \left\{ \frac{(1 + \alpha)c_4}{m} E[\text{tr}(\Delta^{-1} F^2)] - \frac{2n_1}{n_2 - m - 1} + 2E \left[ \frac{\text{tr} \Delta^{-1}}{\text{tr } F^{-1}} \right] \right.
\]
\[ -(1 - \alpha)E \left[ \frac{mc_4 \text{tr} \Delta^{-2}}{(\text{tr } F^{-1})^2} \right] - 2\alpha c_4 E \left[ \frac{\text{tr} (\Delta^{-2} F)}{\text{tr } F^{-1}} \right] \}.
\]

Using Corollary 2.4 in Konno (1988), it can be shown that \( E[\text{tr}(\Delta^{-1} F^2)] = mn_1/[c_4(n_2 - m - 1)] \). Applying the upper bounds (i) and (ii) in Lemma 1,

(3.7) \[ G_2(\Delta) \geq (1 - \alpha)mc_4 \left\{ \frac{(1 + \alpha)n_1 - 2n_1}{n_2 - m - 1} + 2E \left[ \frac{\text{tr} \Delta^{-1}}{\text{tr } F^{-1}} \right] \right.
\]
\[ - (1 - \alpha)mc_4 \frac{(n_1 - m + 3)}{n_2 - 4} E \left[ \frac{\text{tr} \Delta^{-1}}{\text{tr } F^{-1}} \right] \]
\[ - \frac{2c_4\alpha(n_1 + 2)(n_2 - 2) - 2(m - 1)}{(n_2 - m - 1)(n_2 - 4)} E \left[ \frac{\text{tr} \Delta^{-1}}{\text{tr } F^{-1}} \right] \}.
\]

Note that there are three expectation terms in (3.7). The coefficient of the first expectation is positive while the last two are negative. Therefore we apply the lower bound of (iii) in Lemma 1 to the first expectation and the upper bound of (iii) to the last two expectation terms and simplify,

(3.8) \[ G_2(\Delta) \geq (1 - \alpha)mc_4(a_1 \alpha - b_1), \]

where \( a_1 \) and \( b_1 \) are given in (3.5) and (3.6). A sufficient condition for \( G_2(\Delta) \geq 0 \) is \( b_1/a_1 \leq \alpha < 1 \). Conditions (3.1) and (3.2) are needed to ensure \( b_1/a_1 < 1 \). Condition (3.3) is to ensure \( a_1 \geq 0 \) and the proof is completed.

Remark 4. It is easy to see that the 'optimal' value for \( \alpha \) that maximizes the lower bound in (3.7) is \( \alpha_2 = (a_1 + b_1)/(2a_1) \) where \( a_1 \) and \( b_1 \) is given in (3.5) and (3.6) respectively.
Table 1. Minimum integer value of $n_2$ satisfy conditions (3.3) and (3.4).

**Remark 5.** The conditions (3.2) and (3.3) in Theorem 3.1 seem rather restrictive. Table 1 gives the minimum integer value of $n_2$ that satisfy (3.2) and (3.3) for various combinations of $m$ and $n_1$. From Table 1, the condition on $n_2$ becomes less and less restrictive when $m$ increase.

For the problem of estimating $\Sigma$ in a Wishart distribution, similar results can be obtained from Theorem 3.1 by letting $n_2 \to \infty$ and replace $n_1$ by $n$.

**Theorem 3.2.** Assume that $m > 3$ and $n > m + 3 + 12/(m - 3)$. Applying the loss function (1.3),

\[
\tilde{\mathcal{L}}_2(\alpha) = \alpha c_2 S + (1 - \alpha) c_2 \frac{m}{\text{tr} S^{-1}} I_m
\]

dominates the best linear estimator $c_2 S$ (where $c_2 = 1/(n+m+1)$) provided that $b_2/a_2 < \alpha < 1$ where

\begin{align*}
(3.10) & \quad a_2 = [m(n - m + 3) - 2(n + 2)] c_2 (n - m + 1) + n, \\
(3.11) & \quad b_2 = mc_2 (n - m + 3)(n - m + 1) - n + 2m + 2.
\end{align*}

**Proof.** The proof is similar to the proof of Theorem 2.2. As $n_2$ tends to infinity, $n_2 F$ converges to a Wishart matrix with $n_1$ degrees of freedom and scale matrix $\Delta$. This is same as the setting in Theorem 3.2 with $n$ replace $n_1$ and $\Sigma$ replace $\Delta$. The results in Theorem 3.2 can be obtained from Theorem 3.1 by letting $n_2 \to \infty$ in (3.8). Note that

\[
\lim_{n_2 \to \infty} c_4 a_1 = c_2 a_2 \quad \text{and} \quad \lim_{n_2 \to \infty} c_4 b_1 = c_2 b_2
\]

where $a_1, b_1$ are defined in (3.5) and (3.6), and $a_2, b_2$ are defined in (3.10) and (3.11) respectively. Therefore the risk difference between $c_2 S$ and $\tilde{\mathcal{L}}_2(\alpha)$ is

\[
G_3(\Sigma) \geq (1 - \alpha) mc_2 (a_2 \alpha - b_2).
\]

A sufficient condition for $G_3(\Sigma) > 0$ is $b_2/a_2 < \alpha < 1$. Note that $b_2/a_2 < 1$ iff $(n+2)(n-m+1) < (n-m-1)(n+m+1)$, which is equivalent to $n(m-3) > m^2 + 3$. Therefore
Table 2. PRIAL of $\hat{\Sigma}_1(\alpha)$ over $c_1 S$ using $L_1$ loss.
\[
\begin{array}{lcc}
\Sigma & n = 5 & n = 10 & n = 25 \\
\text{diag}(1,1,1) & 9.633 & 7.296 & 3.765 \\
\text{diag}(4,2,1) & 9.293 & 6.799 & 3.468 \\
\text{diag}(25,1,1) & 8.917 & 6.207 & 3.292 \\
\end{array}
\]

Table 3. PRIAL of $\hat{\Sigma}_2(\alpha)$ over $c_2 S$ using $L_2$ loss.
\[
\begin{array}{lcc}
\Sigma & n = 20 & n = 25 & n = 50 \\
\text{diag}(1,1,1,1) & 0.110 & 0.450 & 0.651 \\
\text{diag}(8,4,2,1) & 0.105 & 0.422 & 0.599 \\
\text{diag}(25,1,1,1) & 0.106 & 0.430 & 0.632 \\
\end{array}
\]

the conditions $m > 3$ and $n > m + 3 + 12/(m - 3)$ are needed to ensure $b_2/a_2 < 1$ as stated in (3.1). The conditions (3.2) and (3.3) are satisfied as $n_2 \to \infty$.

**Remark 6.** An ‘optimal’ value of $\alpha$ that maximizes the lower bound of $G_3(\Sigma)$ in (3.12) is

$$
\alpha_3 = \frac{(a_2 + b_2)}{(2a_2)} = \frac{[m(n - m + 3) - n - 2](n - m + 1) + (m + 1)(n - m - 1)}{[m(n - m + 3) - 2n - 4](n - m + 1) + n(n - m - 1)}.
$$

Note also that $\alpha_3 < 1$ iff $b_2 < a_2$. Hence the conditions $n > m + 3 + 12/(m - 3)$ and $m > 3$ in Theorem 3.2 ensure that $\alpha_3 < 1$.

4. Simulation study

For estimating the covariance matrix $\Sigma$ in the Wishart distribution, a Monte Carlo simulation study was carried out to compare the risks of $\hat{\Sigma}_1(\alpha)$ and $c_1 S$ using $L_1$ loss with the ‘optimal’ value of $\alpha$ suggested in Remark 3. For $m = 3$ and $n = 5, 10, 25$, a sample of 1000 Wishart $W_3(n, \Sigma)$ matrices were generated for three different choices of $\Sigma$. Then these 1000 matrices were used to construct $c_1 S$ and $\hat{\Sigma}_1(\alpha)$ and the average losses (with respect to $L_1$) were obtained. Table 2 summarizes the percentage reduction in average loss (PRIAL) for $\hat{\Sigma}_1(\alpha)$ compared to $c_1 S$, i.e., it is the estimate of

$$
\frac{E[L_1(\Sigma, c_1 S) - L_1(\Sigma, \hat{\Sigma}_1(\alpha))]}{E[L_1(\Sigma, c_1 S)]}.
$$

Similarly we also compare the risks of $\hat{\Sigma}_2(\alpha)$ and $c_2 S$ using $L_2$ loss with the ‘optimal’ value of $\alpha$ suggested in remark 6. Due to the conditions stated in Theorem 3.2, we choose $m = 4$ and $n = 20, 25, 50$ in this simulation. Table 3 shows the PRIAL for $\hat{\Sigma}_2(\alpha)$ compared to $c_2 S$ using $L_2$ loss.

For estimating $\Delta$ in a multivariate $F$ distribution, we generate 1000 random matrices of $A$'s and $B$'s from $W_m(n_1, \Delta)$ and $W_m(n_2, I)$ respectively for three different choices of
$\Delta$. They are then transformed into $F = A^{1/2}B^{-1}A^{1/2}$. For simplicity, we restrict $n_1 = n_2$ in our simulation study. For the $L_1$ loss, we choose $m = 3$ and $n_1 = n_2 = 5, 10, 25$. Table 4 summarizes the PRIAL for $\hat{\Delta}_1(\alpha)$ compared to $c_3F$ with the ‘optimal’ value of $\alpha$ suggested in Remark 1. For the $L_2$ loss, we choose $m = 8$ since $n_2 = n_1$ can assume reasonable values that satisfy the conditions in (3.3) and (3.4) as seen from Table 1. Therefore, we choose $m = 8$ and $n_1 = n_2 = 40, 45, 50$ in this study. The PRIAL for $\hat{\Delta}_2(\alpha)$ compared to $c_4F$ with the “optimal” value of $\alpha$ suggested in Remark 4.

From Tables 2–5, all the PRIALs are positive and confirm the dominance results. Our proposed estimators represent a reasonably improvement over the corresponding best linear estimators except for estimating $\Sigma$ in a Wishart distribution using the $L_2$ loss.

Appendix

Suppose that a random $m \times m$ positive definite matrix $F = (f_{ij})$ has a multivariate $F$ distribution with degrees of freedom $n_1$ and $n_2$ and scale matrix $\Delta$, denoted by $F_m(n_1, n_2; \Delta)$. That is, $F$ has the probability density function

$$
\frac{\Gamma_m(n/2)}{\Gamma_m(n_1/2)\Gamma_m(n_2/2)} |\Delta|^{-n_1/2} |F|^{(n_1 - m - 1)/2} |I + \Delta^{-1}F|^{-n/2}
$$

where $n = n_1 + n_2$, $n_1 > m + 1$, $n_2 > m + 1$ and $\Gamma_m(\cdot)$ is the multivariate Gamma function. Let $V(F, \Delta)$ be a matrix whose elements are function of $F$ and $\Delta$ and $V(r) = rV + (1 - r) \text{diag}(V)$. Note that $\text{tr}(A(r)B(1/r)) = \text{tr}(AB)$ for any $m \times m$ matrices $A$ and $B$. We define

$$
D = (d_{ij}) = \frac{1}{2} (1 + \delta_{ij}) \frac{\partial}{\partial f_{ij}}
$$  

(A.1)
as a matrix of differential operators where $\delta_{ij}$ is the Kronecker delta. $DV$ is the formal matrix product of $D$ and $V$. Let $h(F)$ be a real-valued function of $F$ and $\partial h(F)/\partial F$ is an $m \times m$ matrix whose $(i, j)$-th element is $\partial h(F)/\partial f_{ij}$. We simply write $V(F, \Delta)$ as $V$ and $h(F)$ as $h$ for brevity. Under fairly general regularity conditions, we have the $F$ identity:

$$E[h \, \text{tr}(\Delta + F)^{-1} V] = \frac{2}{n} E[h \, \text{tr}(D V)] + \frac{2}{n} E \left[ \text{tr} \left( \frac{\partial h}{\partial F} V^{(1/2)} \right) \right] + \frac{n_1 - m - 1}{n} E[h \, \text{tr}(F^{-1} V)].$$

This $F$ identity is an extension of the Wishart identity (Haff (1979)) to the multivariate $F$ distribution. The regularity conditions are to ensure the function $hV$ satisfies the conditions of the Stokes’ theorem and are given in Konno (1988).

**Proof of Lemma 1.** (i) Take $h(F) = 1/(\text{tr} F^{-1})^2$ and $V = (\Delta + F)\Delta^{-2}$ in the $F$ identity (A.2). Note that $\text{tr} \, DV = [(m + 1)/2] \, \text{tr} \Delta^{-2}$ and $\partial h/\partial F = 2F^{-2}(\Delta + F)/(\text{tr} F^{-1})^3$ (see Haff (1979)). Therefore,

$$E \left[ \frac{\text{tr}(\Delta^{-2})}{(\text{tr} F^{-1})^2} \right] = \frac{n_1}{n} E \left[ \frac{\text{tr}(\Delta^{-2})}{(\text{tr} F^{-1})^2} \right] + \frac{4}{n} E \left[ \frac{\text{tr} F^{-2}(\Delta + F)\Delta^{-2}}{(\text{tr} F^{-1})^3} \right] + \frac{n_1 - m - 1}{n} E \left[ \frac{\text{tr}(F^{-1} \Delta^{-1})}{(\text{tr} F^{-1})^2} \right].$$

Using $\text{tr}[F^{-2}(\Delta + F)\Delta^{-2}] \leq (\text{tr} F^{-1})[\text{tr}(F^{-1}(\Delta + F)\Delta^{-2})]$ and simplify,

$$E \left[ \frac{\text{tr}(\Delta^{-2})}{(\text{tr} F^{-1})^2} \right] \leq \frac{n_1 - m + 3}{n_2 - 4} E \left[ \frac{\text{tr}(F^{-1} \Delta^{-1})}{(\text{tr} F^{-1})^2} \right].$$

It is same as equation (A.1) in Konno (1991). Using

$$\text{tr}(F^{-1} \Delta^{-1}) \leq (\text{tr} F^{-1})(\text{tr} \Delta^{-1}),$$

the result (i) follows immediately.

(ii) Take $h(F) = 1/(\text{tr} F^{-1})$ and $V = (\Delta + F)\Delta^{-2} F$ in (A.2). $\partial h/\partial F = F^{-2}(\Delta + F)/(\text{tr} F^{-1})^2$ (see Haff (1979)) and using Lemma (2.2) in Konno (1988), it can be shown that $\text{tr} \, DV = [(m + 1)/2](\text{tr} \Delta^{-1}) + (m + 1) \, \text{tr}(\Delta^{-2} F)$.

$$E \left[ \frac{\text{tr}(\Delta^{-2} F)}{\text{tr} F^{-1}} \right] = \frac{n_1}{n_2 - m - 1} E \left[ \frac{\text{tr} \Delta^{-1}}{\text{tr} F^{-1}} \right] + \frac{2}{n_2 - m - 1} E \left[ \frac{\text{tr}(\Delta^{-1} F^{-1})}{(\text{tr} F^{-1})^2} \right] + \frac{2}{n_2 - m - 1} E \left[ \frac{\text{tr} \Delta^{-2}}{(\text{tr} F^{-1})^2} \right].$$

Applying (A.3) in the second term and (i) in the last term of the right hand side of (A.4), the result (ii) follows after simplification.
(iii) Take $h(F) = 1/(\text{tr} F^{-1})$ and $V = (\Delta + F)\Delta^{-1}$ in (A.2). Note that $\text{tr} DV = [(m + 1)/2](\text{tr} \Delta^{-1})$ and $\partial h/\partial F = F^{-2}((\text{tr} F^{-1})^2$ (see Haff (1979)).

\begin{equation}
E \left[ \frac{\text{tr} \Delta^{-1}}{\text{tr} F^{-1}} \right] = \frac{n_1 - m - 1}{n_2} + \frac{2}{n_2} E \left[ \frac{\text{tr} F^{-2}}{(\text{tr} F^{-1})^2} \right] + \frac{2}{n_2} \left[ \frac{\text{tr}(F^{-1}\Delta^{-1})}{(\text{tr} F^{-1})^2} \right].
\end{equation}

Note that the last two terms of (A.5) are nonnegative, the lower bound in (iii) follows. For the upper bound in (iii), we apply (A.3) to the last term of (A.5) and $\text{tr} F^{-2}/(\text{tr} F^{-1})^2 \leq 1$ to the second term of (A.5), which completes the proof.
